Campus Networking Workshop

Networking Fundamentals Refresher
Objectives

- To revise the core concepts
- To ensure we are using the same terminology

What is this?

7	Application

6	Presentation

5	Session

4	Transport

3	Network

2	Link

1	Physical

Layer 1: Physical Layer

- Transfers a stream of *bits*

- Defines physical characteristics
  - Connectors, pinouts
  - Cable types, voltages, modulation
  - Fibre types, lambdas
  - Transmission rate (bps)

- No knowledge of bytes or frames

    `101101` $\longrightarrow$

Examples of Layer 1 technologies and standards?
Types of equipment

- Layer 1: **Hub, Repeater, Media Convertor**

- Works at the level of individual bits

- All data sent out of all ports

- Hence data may end up where it is not needed

Building networks at Layer 1

- What limits do we hit?

Layer 2: (Data)Link Layer

- Organises data into *frames*
- <u>May</u> detect transmission errors (corrupt frames)
- <u>May</u> support shared media
  - Addressing (unicast, multicast) – who should receive this frame
  - Access control, collision detection
- Usually identifies the layer 3 protocol being carried
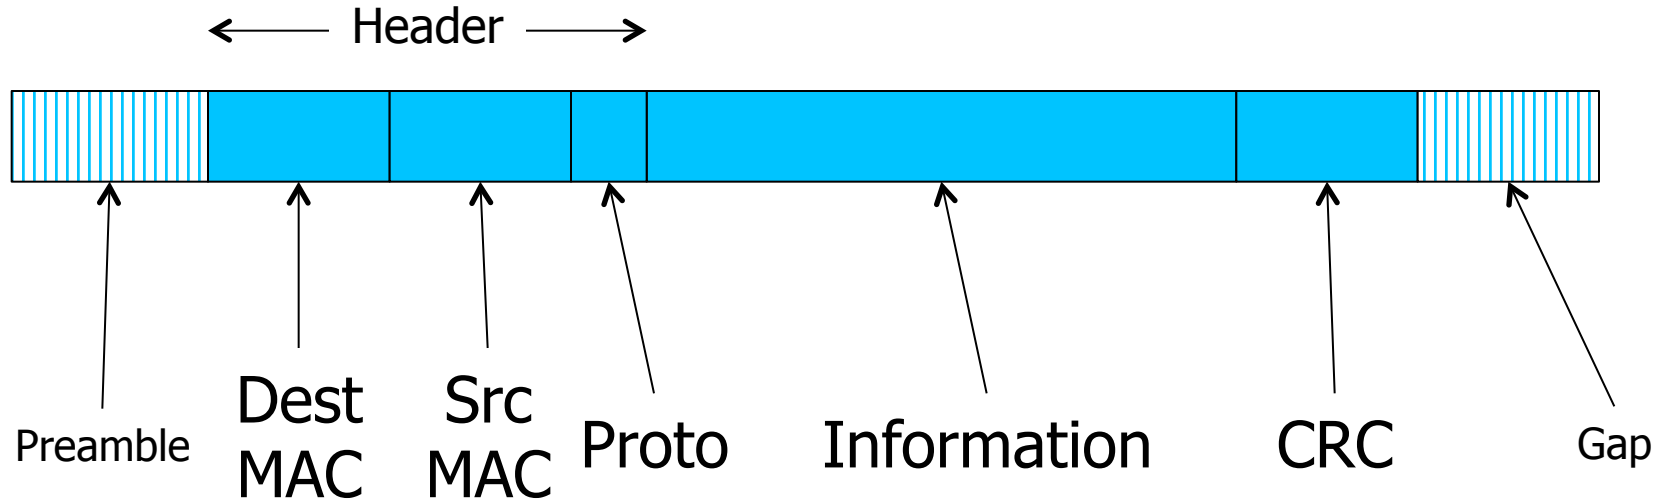

Example Layer 2: SLIP

Flag   Information   Flag
- That's it!

Example Layer 2: PPP

Flag Protocol Information CRC Flag
- Also includes link setup and negotiation
  - Agree link parameters (LCP)
  - Authentication (PAP/CHAP)
  - Layer 3 settings (IPCP)

Example Layer 2: Ethernet

←——— Header ———→

| Preamble | Dest MAC | Src MAC | Proto | Information | CRC | Gap |

- MAC addresses
- Protocol: 2 bytes
  - e.g. 0800 = IPv4, 0806 = ARP, 86DD = IPv6
- Preamble: carrier sense, collision detection

Types of equipment (contd)

- Layer 2: **Switch, Bridge**
- Receives whole layer 2 frames and selectively retransmits them
- Learns which MAC addr is on which port
- If it knows the destination MAC address, will send it out only on that port
- Broadcast frames must be sent out of all ports, just like a hub
- Doesn't look any further than L2 header
Building networks at Layer 2

- What limits do we hit?
Layer 3: (Inter)Network Layer

- Connects Layer 2 networks together
  - Forwarding data from one network to another
- Universal frame format (datagram)
- Unified addressing scheme
  - Independent of the underlying L2 network(s)
  - Addresses organised so that it can scale globally (aggregation)
- Identifies the layer 4 protocol being carried
- Fragmentation and reassembly

Example Layer 3: IPv4 Datagram

Header

Version, length, flags, fragments

TTL

Proto

hdr csum

Src IP

Dest IP

Information

- Src, Dest: IPv4 addresses

- Protocol: 1 byte
  - e.g. 6 = TCP, 17 = UDP (see /etc/protocols)

Types of equipment (contd)

- Layer 3: **Router**

- Looks at the dest IP in its Forwarding Table to decide where to send next

- Collection of routers managed together is called an "Autonomous System"

- The forwarding table can be built by hand (static routes) or dynamically

  - Within an AS: IGP (e.g. OSPF, IS-IS)

 - Between ASes: EGP (e.g. BGP)

Traffic Domains
Network design guidelines

- No more than ~250 hosts on one subnet

  - Implies: subnets no larger than /24

- Campus guideline: one subnet per building

  - More than one may be required for large buildings

Layer 4: Transport Layer

- Identifies the *endpoint process*
  - Another level of addressing (port number)
- <u>May</u> provide reliable delivery
  - Streams of unlimited size
  - Error correction and retransmission
  - In-sequence delivery
  - Flow control
- Or might just be unreliable datagram transport

Example Layer 4: UDP

Header

Src Port   Dst Port   Len   Checksum   Information
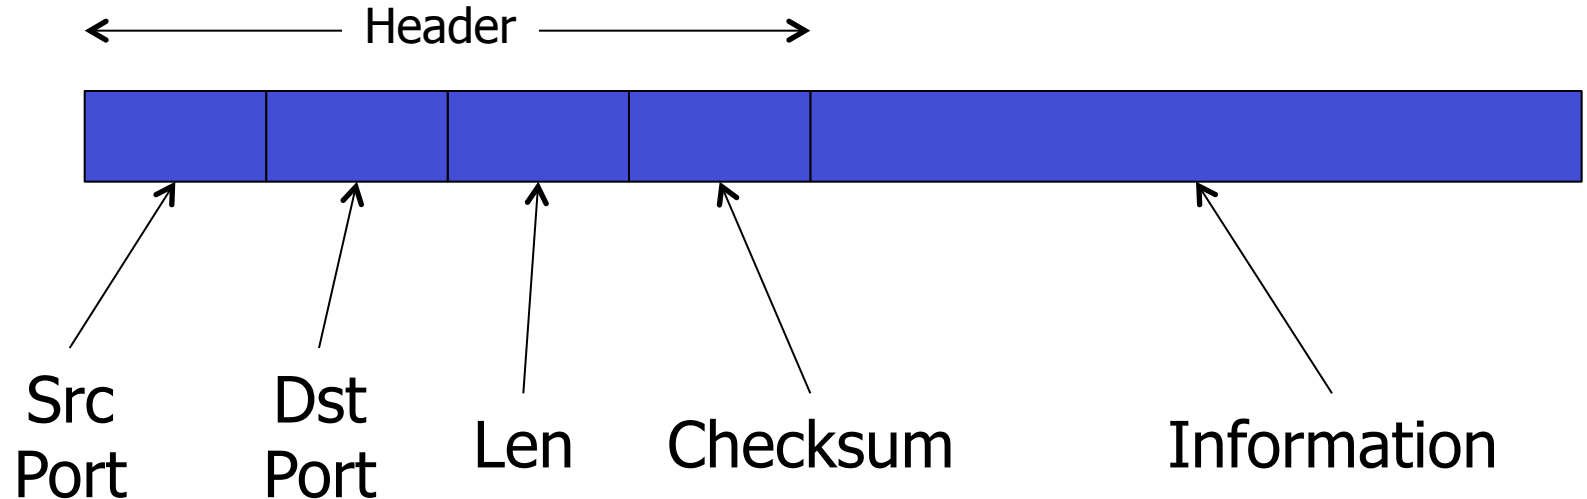

- Port numbers: 2 bytes
  - Well-known ports: e.g. 53 = DNS
  - Ephemeral ports: ≥1024, chosen dynamically by client

Layers 5 and 6

- Session Layer: long-lived sessions
    - Re-establish transport connection if it fails
    - Multiplex data across multiple transport connections
- Presentation Layer: data reformatting
    - Character set translation
- Neither exist in the TCP/IP suite: the application is responsible for these functions
Layer 7: Application layer

- The actual work you want to do
- Protocols specific to each application
- *Examples?*

Encapsulation

- Each layer provides services to the layer above

- Each layer makes use of the layer below

- Data from one layer is *encapsulated* in frames of the layer below

Encapsulation in action

| L2 hdr | L3 hdr | L4 hdr | Application data |

- L4 segment contains part of stream of application protocol
- L3 datagram contains L4 segment
- L2 frame contains L3 datagram in its data portion

For discussion

- Can you give examples of equipment which operates at layer 4? At layer 7?

- At what layer does a wireless access point work?

- What is a "Layer 3 switch"?

- How does traceroute find out the routers which a packet traverses?

Addressing at each layer

- What do the addresses look like?

- How do they get allocated, to avoid conflicts?

- Examples to consider:
    - L2: Ethernet MAC addresses
    - L3: IPv4, IPv6 addresses
   - L4: TCP and UDP port numbers

IPv4 addresses

- 32-bit binary number

  - How many unique addresses in total?

- Conventionally represented as four dotted decimal octets
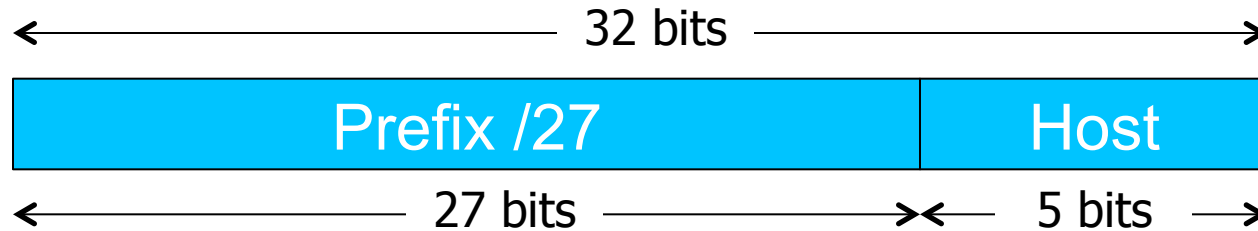

10000000110111111100111010100010011

128 . 223 . 157 . 19

# Hierarchical address allocation

Prefixes

- A range of IP addresses is given as a *prefix*, e.g. 192.0.2.128/27

- In this example:

    - How many addresses are available?

    - What are the lowest and highest addresses?

IPv4 "Golden Rules"

1. All hosts on the same L2 network must share the *same* prefix

2. All hosts on the same subnet have *different* host part

3. Host part of all-zeros and all-ones are reserved

Subnetting Example

- You have been given 192.0.2.128/27

- However you want to build two Layer 2 networks and route between them

- The Golden Rules demand a different prefix for each network

- Split this address space into two equal-sized pieces

  - What are they?

IPv6 addresses

- 128-bit binary number

- Conventionally represented in hexadecimal
  – 8 words of 16 bits, separated by colons

  2001:0468:0d01:0103:0000:0000:80df:9d13

- Leading zeros can be dropped

- One contiguous run of zeros can be replaced by ::

  2001:468:d01:103::80df:9d13

IPv6 rules

- With IPv6, every network prefix is /64

  - (OK, some people use /127 for P2P links)

- The remaining 64 bits can be assigned by hand, or picked automatically

  - e.g. derived from NIC MAC address

- There are special prefixes

  - e.g. link-local addresses start fe80::

- Total available IPv6 space is ≈ 2^{61} subnets

- Typical end-user allocation is /48 (or /56)

Debugging Tools

- What tools can you use to debug your network
  - At layer 1?
  - At layer 2?
  - At layer 3?
  - Higher layers?

Other pieces

- What is MTU? What limits it?
- What is ARP?
  - Where does it fit in the model?
- What is ICMP?
  - Where does it fit in the model?
- What is NAT? PAT?
  - Where do they fit in the model?
- What is DNS?
  - Where does it fit in the model?
