

# Introduction to OSPF

## ISP Workshops

# OSPF

---

- Open Shortest Path First
- Open:
  - Meaning an Open Standard
  - Developed by IETF (OSPF Working Group) for IP – RFC1247
  - Current standard is OSPFv2 (RFC2328)
- Shortest Path First:
  - Edsger Dijkstra's algorithm for producing shortest path tree through a graph
    - Dijkstra, E. W. (1959). "A note on two problems in connexion with graphs". *Numerische Mathematik* **1**: 269–271

# OSPF

---

- Known as a Link State Routing Protocol
  - The other link state routing protocol is ISIS
  - Each node in the network computes the map of connectivity through the network
- The other type of Routing Protocol is Distance Vector
  - Like EIGRP or RIP
  - Each node shares its view of the routing table with other nodes

# OSPF

---

- Routers with OSPF enabled on them look for neighbouring routers also running OSPF
  - Using the “Hello” protocol
  - The “Hello” packet includes the subnet mask, list of known neighbours, and details such as “hello interval” and “router dead interval”
    - Hello interval – how often the router will send Hellos
    - Router dead interval – how long to wait before deciding router has disappeared
    - The values of “hello interval”, “router dead interval” and subnet mask **must** match on both neighbours
  - When a neighbouring router responds with matching details, a neighbour relationship is formed

# OSPF Neighbour Relationships

---

- A relationship is formed between selected neighbouring routers for the purpose of exchanging routing information
  - This is called an **ADJACENCY**
- Not every pair of neighbouring routers become adjacent
  - On multi-access networks (e.g. ethernet), only selected routers form adjacencies

# OSPF Adjacencies

---

- ❑ Once an adjacency is formed, neighbours share their link state information
  - Information goes in a **Link State Packet** (LSP)
  - LSPs sent to a neighbour are known as **Link State Announcements** (LSA)
- ❑ New information received from neighbours is used to compute a new view of the network
- ❑ On a link failure
  - New LSPs are flooded
  - The routers recompute the routing table

# OSPF across a network

---

- ❑ All routers across the network form neighbour relationships with their directly attached neighbours
- ❑ Each router computes the routing table
- ❑ Once each router has the same view of the network, the network has **converged**
- ❑ The IGP design for a network is crucially important to ensure **scalability** and **rapid convergence**
- ❑ Generally: **the fewer the prefixes, the faster the convergence**

# OSPF Areas

---

- OSPF has the concept of areas
  - All networks must have an area 0, the “default” area
  - Areas are used to scale OSPF for large networks
  - There are many types of areas, to suit many different types of infrastructure and topologies
  - Most small to medium networks (up to ~300 routers) can happily use a single area

# OSPF

---

- OSPFv2 is for IPv4
  - For carrying IPv4 prefixes only
- OSPFv3 is for IPv6
  - For carrying IPv6 prefixes only
  - Based on OSPFv2 but is specifically for IPv6
  - Documented in RFC5340
  - Is totally independent of OSPFv2
- Configuration concepts and syntax are very similar
  - (There are subtle differences/improvements)

# Links in OSPF

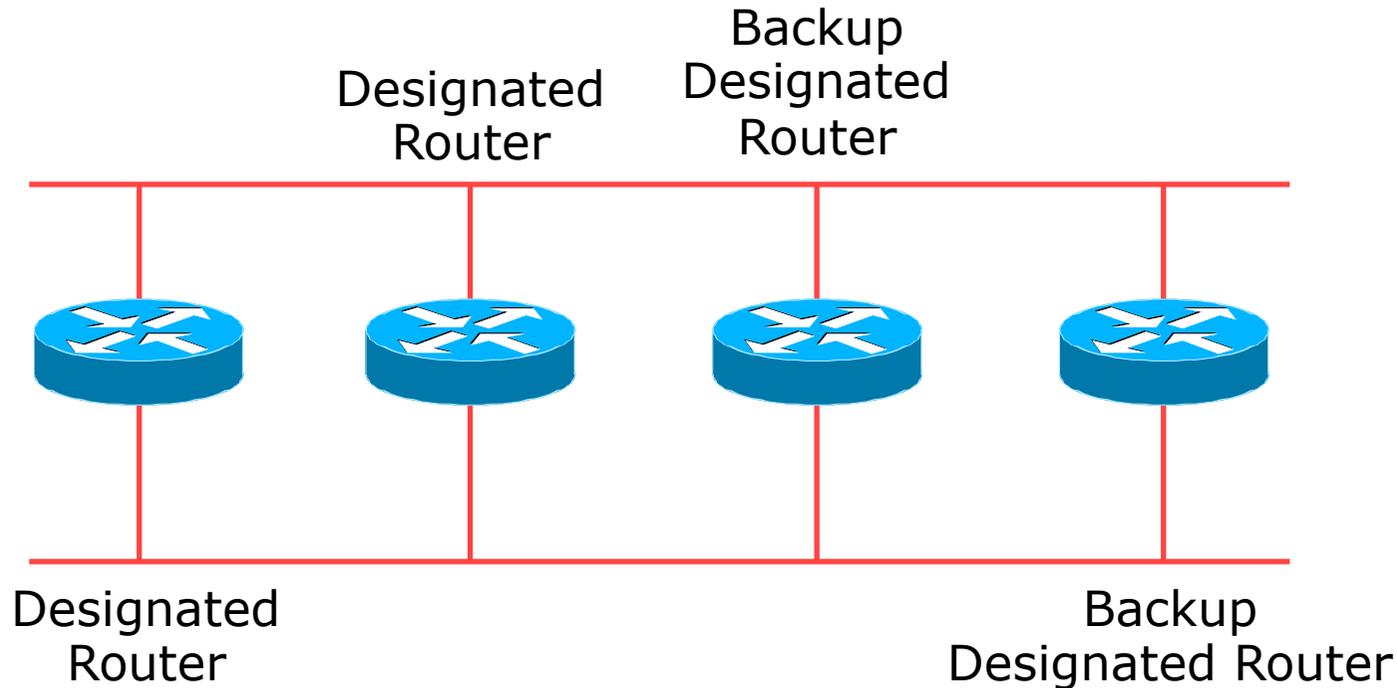

---

- Two types of links in OSPF:
  - Point-to-point link
    - Only one other router on the link, forming a point-to-point adjacency
  - Multi-access network (e.g. ethernet)
    - Potential for many other routers on the network, with several other adjacencies
- OSPF in multi-access networks has optimisations to aid scaling
  - Two routers are elected to originate the LSAs for the whole multi-access network
  - Called “**Designated Router**” and “**Backup Designated Router**”
  - Other routers on the multi-access network form adjacencies with the DR and BDR

# Designated Router

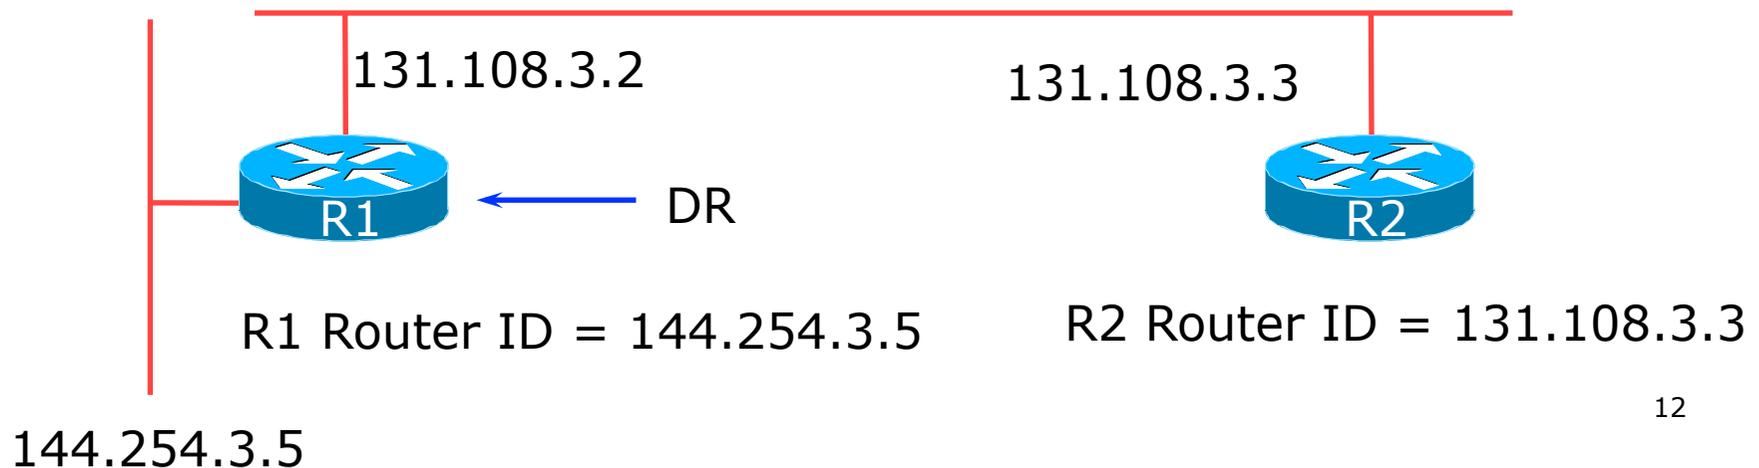

---

- There is ONE designated router per multi-access network
  - Generates network link advertisements
  - Assists in database synchronization
  - Scales OSPF for multi-access (ethernet) networks

# Selecting the Designated Router

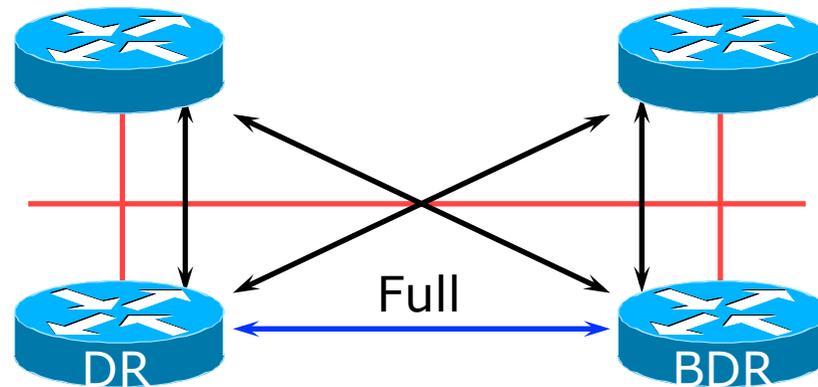

- ❑ Configured priority (per interface)
  - Configure high priority on the routers to be the DR/BDR
- ❑ Else priority determined by highest router ID
  - Router ID is 32 bit integer
  - Set manually, otherwise derived from the loopback interface IPv4 address, otherwise the highest IPv4 address on the router

# Adjacencies on multi-access networks

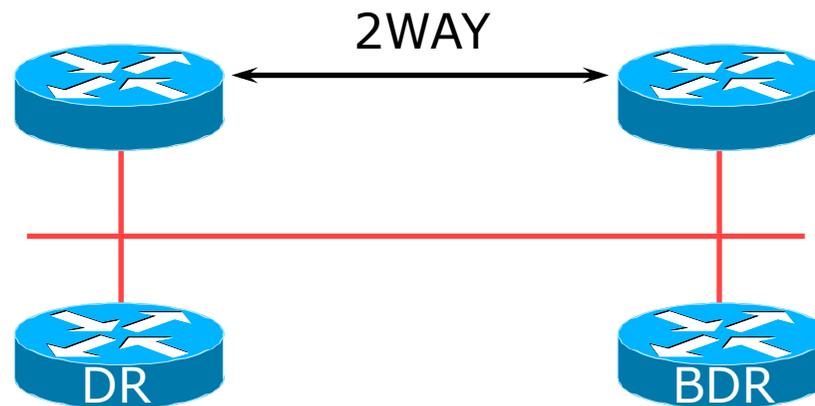

---

- DR and BDR form **FULL** adjacencies:
  - With each other
  - With all other routers on the multi-access network
  - Databases are synchronised
  - LSAs propagate along adjacencies

# Adjacencies on multi-access networks

- Neighbour relationships between routers which are not DR or BDR are called **2WAY**
  - They see each other in HELLO packets but do not exchange topology information
  - The neighbours then are **not adjacent**

# Adjacencies: Examples

---

- To find adjacency state, use:

```
show ip[v6] ospf neighbor
```

- Point-to-Point link

Neighbor ID	Pri	State	Dead Time	Address	Interface
10.10.15.236	0	FULL/ -	00:00:35	10.10.15.16	Serial1/0

- FULL: other router to DR/BDR

Neighbor ID	Pri	State	Dead Time	Address	Interface
10.10.15.225	1	FULL/BDR	00:00:35	10.10.15.2	FastEth0/0
10.10.15.226	1	FULL/DR	00:00:35	10.10.15.3	FastEth0/0

- 2WAY: other router to other router

Neighbor ID	Pri	State	Dead Time	Address	Interface
10.10.15.227	1	2WAY/DROTHER	00:00:35	10.10.15.4	FastEth0/0

# OSPF on Cisco IOS

---

- ❑ Starting OSPFv2 (IPv4) in Cisco's IOS
  - `router ospf 42`
  - Where "42" is the process ID
- ❑ Starting OSPFv3 (IPv6) in Cisco's IOS
  - `ipv6 router ospf 42`
  - Where "42" is the process ID
- ❑ OSPF process ID is unique to the router
  - Gives possibility of running multiple instances of OSPF on one router
  - Process ID is not passed between routers in an AS
  - **Some ISPs configure the process ID to be the same as their BGP Autonomous System Number**

# Adding interfaces to OSPF

---

## □ OSPF interface configuration:

- When OSPF is configured for a subnet or on an interface, the router will automatically attempt to find neighbours on that subnet or interface
- ISP Best Practice is to disable this behaviour:

```
router ospf 42  
  passive-interface default
```

- And then explicitly enable the interface to allow OSPF to search for neighbours as required:

```
router ospf 42  
  no passive-interface POS 4/0
```

# OSPF on Cisco IOS

---

- Enabling OSPF on an interface does **two** things:
  1. Enables the Hello protocol for forming neighbour relationships and adjacencies with other routers connected to that interface
  2. Announces the interface subnet(s) into OSPF
- Care needed
  - Must avoid enabling the Hello protocol on untrusted networks
    - (e.g. those outside your Autonomous System)

# OSPF on Cisco IOS

---

- Forming neighbour relationships
  - OSPF needs to be activated on the interface the neighbour relationship is desired on:

```
interface POS 4/0
  ip address 192.168.1.1 255.255.255.252
  ip ospf 42 area 0
!
router ospf 42
  passive-interface default
  no passive-interface POS 4/0
!
```

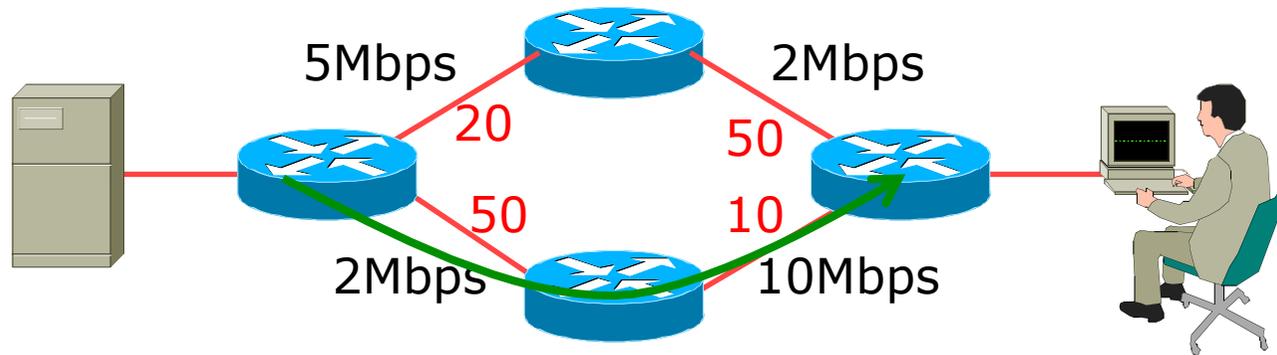

# OSPF interface costs

---

- ❑ Cisco IOS sets the interface cost automatically
  - Formula used:  $\text{cost} = 10^8 / \text{interface bandwidth}$ 
    - ❑ Which is fine for interfaces up to 100Mbps
- ❑ Many operators develop their own interface cost strategy
  - ```
ip ospf cost 100
```
  - Sets interface cost to 100
  - Care needed as the sum of costs determines the best path through the network
- ❑ OSPF chooses lowest cost path through a network
- ❑ OSPF will load balance over paths with equal cost to the same destination

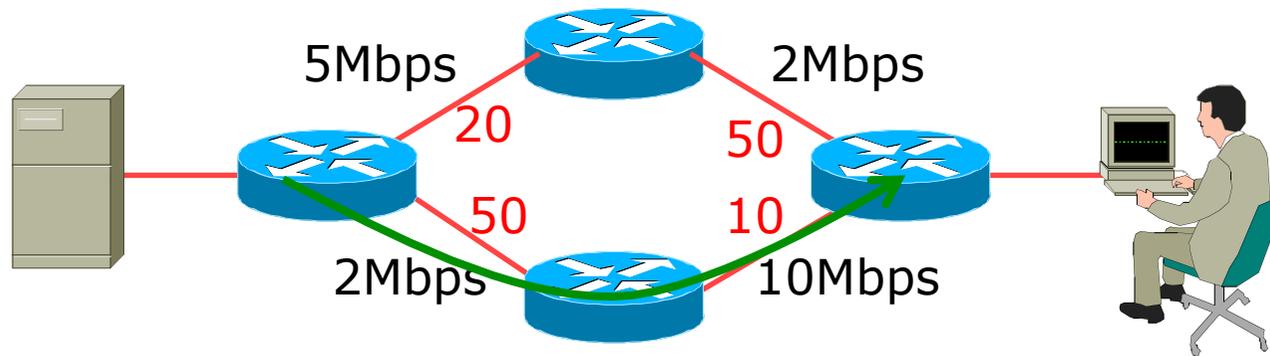

# OSPF Metric Calculation

- Best path/lowest cost = 60

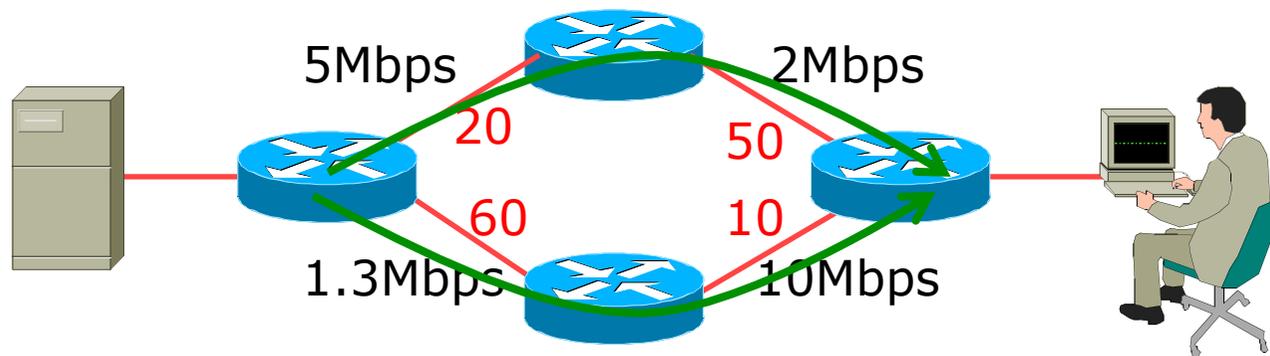

# OSPF Metric Calculation

- Best path/lowest cost = 60

- Equal cost paths = 70

# OSPF Neighbour Authentication

---

- ❑ Neighbour authentication is highly recommended
  - Prevents unauthorised routers from forming neighbour relationships and potentially compromising the network
- ❑ OSPFv2 – Authentication is built-in
  - There are two types:
    - ❑ Plain text password
    - ❑ MD5 hash
- ❑ OSPFv3 – uses standard IP security header
  - There are two types:
    - ❑ MD5 hash
    - ❑ SHA1

# OSPFv2 – Neighbour Authentication

---

- ❑ Configuring authentication for area 0
  - Interfaces still need the authentication key, e.g. POS4/0

```
router ospf 42
  area 0 authentication message-digest
  !
  interface POS 4/0
    ip ospf message-digest-key <key-no> md5 <passwd>
  !
```

- ❑ Configuring authentication per interface:

```
interface POS 4/0
  ip ospf authentication message-digest
  ip ospf message-digest-key <key-no> md5 <passwd>
  !
```

# OSPFv3 – Neighbour Authentication

---

- ❑ Configuring authentication for all interfaces in area 0
  - The key is included in the command turning on authentication for area 0:

```
ipv6 router ospf 42
  area 0 authentication ipsec spi 256 md5 <passwd>
!
```

- ❑ Configuring authentication per interface:

```
interface POS 4/0
  ipv6 ospf authentication ipsec spi 256 md5 <passwd>
!
```

# Other OSPF Features

---

- ❑ Originating a default route into OSPF:

```
router ospf 42
  default-information originate
```

- Which will originate a default route into OSPF if a default route exists in the RIB

- ❑ OSPF on point-to-point ethernet:

- DR and BDR election is not needed on a point to point link – so it is disabled, which is more efficient

```
interface fastethernet0/2
  ip ospf network point-to-point
```

- ❑ There are equivalent commands for OSPFv3

# Conclusion

---

- ❑ OSPF is a Link State Routing Protocol
- ❑ Quick and simple to get started
  - But has a myriad of options and features to cover almost all types of network topology
  - ISPs keep their OSPF design **SIMPLE**
  - ~300 routers in a single area is entirely feasible
