Advanced DNS Operations & Security

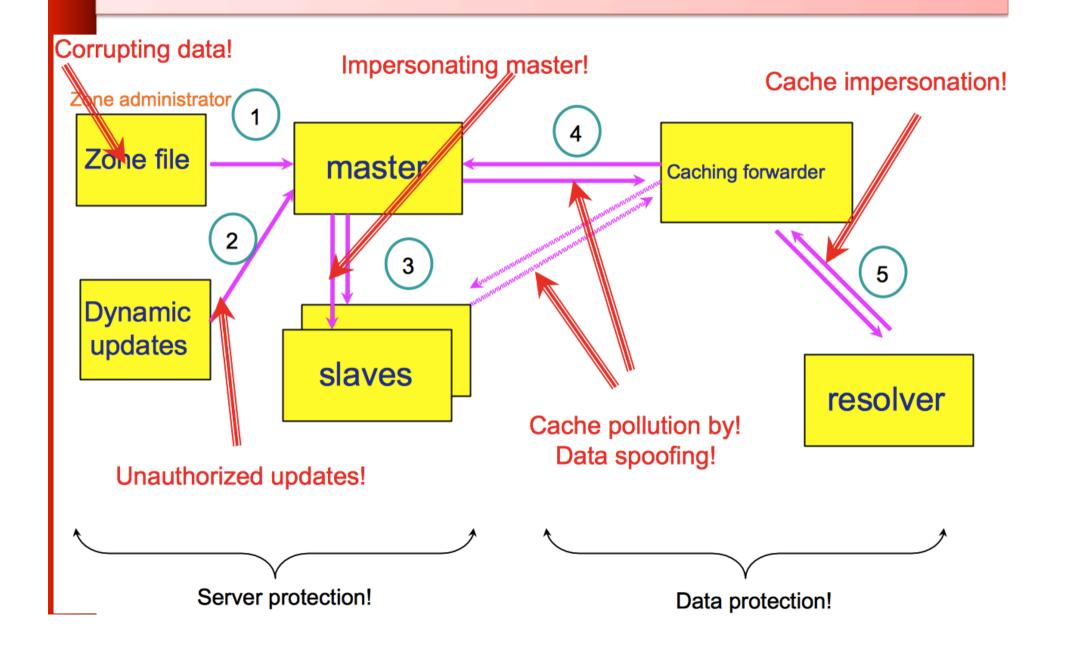

DNS Security - TSIG

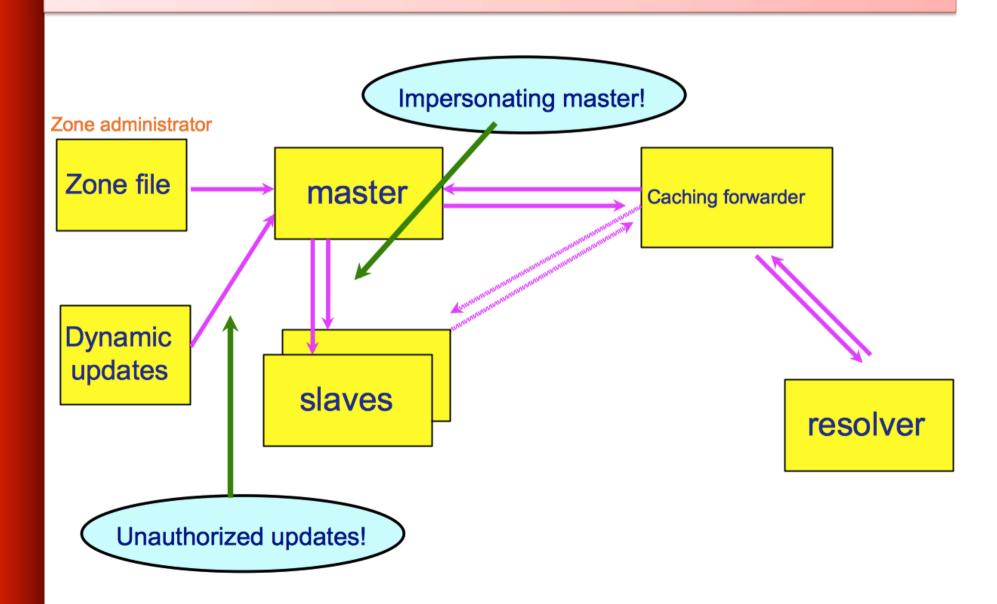

DNS: Data Flow

DNS Vulnerabilities

TSIG protected vulnerabilities

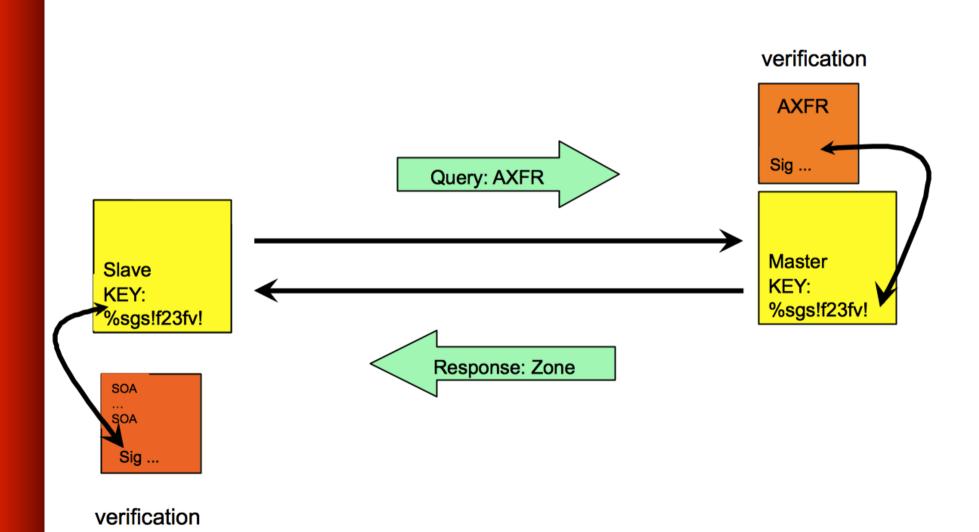

What is TSIG?

- Transaction SIGnature
- A mechanism for protecting communication between name servers and between stub resolvers and nameservers
- A keyed-hash is applied (like a digital signature), so the recipient of the message can verify that it hasn't been tampered with:
 - DNS question / answer
 - timestamp
- Based on a shared secret
 - Both the sender and recipient must be configured with it

What is TSIG?

- RFC 2845 TSIG
- Can also be used to authorize:
 - zone transfers
 - dynamic updates
 - authentication of caching forwarders
- Used in server configuration not in the zone file

TSIG example:

TSIG steps

- 1. Generate secret
- 2. Communicate secret
- 3. Configure servers
- 4. Test

TSIG - Names & Secrets

TSIG name

- A name is given to the key. The name is what is transmitted in the message (so the receiver knows what key the sender has used, out of possibly many)

TSIG secret value

- A value determined during key generation
- Usually seen encoded in BASE64

TSIG – Generating a Secret

- dnssec-keygen
 - Simple tool to generate keys
 - Used here to generate TSIG keys

dnssec-keygen -a <algorithm> -b <bits> -n host <key name>

TSIG – Generating a Secret

Example

dnssec-keygen -a HMAC-MD5 -b 128 -n host ns1-ns2.grp2.net

This will generate a key similar to this:

Kns1-ns2.grp2.net.+157+15921

Files

Kns1-ns2.grp2.net.+157+15921.key

Kns1-ns2.grp2.net.+157+15921.private

TSIG – Generating a Secret

- TSIG keys are never put in the zone files
- There can be some confusion as keys can look like Resource Records:

ns1-ns2.grp2.net. IN KEY 128 157 nEfRx9...bbPn7lyQtE=

TSIG – Configuring servers

- Configuring the key
 - in named.conf, same syntax as for the rndc statement:
- Using the key:

- in named.conf, add:

server x { key; };

... where 'x' is the IP address of the REMOTE server.

Configuration example – named.conf

Primary server 10.10.0.1

Secondary server 10.10.0.2

```
key ns1-ns2.grp2.net {
                                              key ns1-ns2.grp2.net {
   algorithm hmac-md5;
                                                  algorithm hmac-md5;
   secret "APlaceToBe";
                                                  secret "APlaceToBe";
                                              };
};
server 10.10.0.2 {
                                              server 10.10.0.1 {
    keys { ns1-ns2.grp2.net; };
                                                   keys { ns1-ns2.grp2.net; };
};
                                              };
zone "my.test.zone" {
                                              zone "my.test.zone" {
    type master;
                                                   type slave;
    file "db.myzone";
                                                   file "db.myzone.slave";
    allow-transfer {
                                                        masters { 10.10.0.1; };
         key ns1-ns2.grp2.net;
                                                   };
                                              };
    };
```

TSIG – Testing with dig

You can use dig to check TSIG configuration

or

 Wrong key will return "Transfer failed", and a message will be logged in the security category on the server being queried

TSIG - Time!

- TSIG is time sensitive (to avoid replays)
 - message protection expires in 5 minutes
 - make sure time is synchronized! (NTP)
 - for testing, set the time
 - in operations, use NTP!

Questions
